

Method for parallel connection of live wire in distribution box

Summary of Content

In a distribution box, live wires can be connected in parallel to multiple circuit breakers or loads using busbars or junction points, ensuring each load receives the same phase voltage while maintaining proper neutral and earth connections.

Parallel Connection Basics

In a distribution box, parallel connection of live wires means that the incoming phase (live) wire is distributed to multiple branch circuits simultaneously. This is typically done using a busbar or terminal strip, where the main live wire is connected to the busbar, and each branch circuit draws power from it. The neutral wires are connected to a neutral link, and all earth wires are connected to the earth link to ensure safety and proper fault protection .

Single-Pole vs Double-Pole MCBs

- Single-Pole MCBs (SP MCBs): Only the live wire is switched; the neutral is connected directly to the neutral bar. The live wire from the busbar is connected to the input of each SP MCB, and the output goes to the load .
- Double-Pole MCBs (DP MCBs): Both live and neutral wires are switched simultaneously. The live and neutral wires from the busbar or RCCB output are connected to the DP MCB input, and the output goes to the load. This provides better isolation and safety during maintenance .
